Fixed Linear Effects Models

Peter von Rohr

2024-03-18

Extension of Dataset on Body Weight

Animal	ВС	Body Weight	Breed
1	176	471	Angus
2	177	463	Angus
3	178	481	Simmental
4	179	470	Angus
5	179	496	Simmental
6	180	491	Simmental
7	181	518	Limousin
8	182	511	Limousin
9	183	510	Limousin
10	184	541	Limousin

Include Breed into Model

- Breed has an influence on body weight
- Predictor variables must be numeric
- Breed must be converted to numeric code
- Assignment of codes to breeds is rather arbitrary

Breed Codes

Code	Breed
1	Angus
2	Limousin
3	Simmental

In R: Encoding based on alpha-numeric order of factor names

```
levels(as.factor(tbl_bw_bc_breed$Breed))

[1] "Angus" "Limousin" "Simmental"

as.integer(as.factor(tbl_bw_bc_breed$Breed))
```

[1] 1 1 3 1 3 3 2 2 2 2

Dataset with Breed Codes

Animal	Body Weight	Breed	Breed Code
1	471	Angus	1
2	463	Angus	1
3	481	Simmental	3
4	470	Angus	1
5	496	Simmental	3
6	491	Simmental	3
7	518	Limousin	2
8	511	Limousin	2
9	510	Limousin	2
10	541	Limousin	2

Modelling Effect of Breed

- ▶ Simplification: "breed" is the only predictor, ignore BC
- \blacktriangleright Take breed code of animal i as the predictor value x_i
- \blacktriangleright Expected body weight (y_i) for animal i

$$E(y_i) = b_0 + b_1 x_i$$

Problems

- Nothing wrong with previous model
- ▶ But the following relations might give a hint to some problems

$$\left. \begin{array}{l} \text{Animal i of breed Angus} \\ \text{Animal j of breed Limousin} \\ \text{Animal k of breed Simmental} \end{array} \right\} \rightarrow \left\{ \begin{array}{l} E(y_i) = b_0 + b_1 * 1 \\ E(y_j) = b_0 + b_1 * 2 \\ E(y_k) = b_0 + b_1 * 3 \end{array} \right.$$

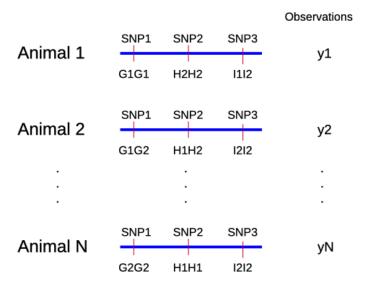

This means, for expected differences between body weights of animals of different breeds

$$\begin{split} E(y_j) - E(y_i) &= E(y_k) - E(y_j) = b_1 \\ E(y_k) - E(y_i) &= 2*b_1 \end{split}$$

Consequences

- Allocation of numerical codes imposes relations between expected values
- Relations might be unreasonable
- Regression analysis only yields estimates for b_0 and b_1 , effects of other breeds are determined
- Conclusion: regression on numerical codes of discrete variables are in most cases unreasonable
- Exception: Estimation of marker effects

Linear Regression Analysis for Genomic Data

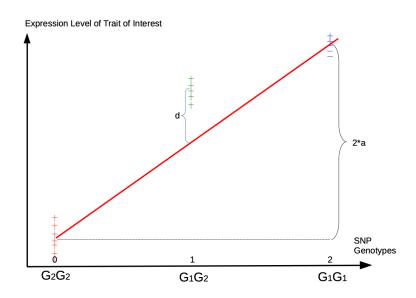

Marker Effect Estimation

- Assume: marker and QTL are very close, such they can no longer be distinguished
- lackbox Fit regression of observations (y) on marker genotypes of locus G
- Assume G_1 is the allele with a positive effect on observed trait
- Use the following encoding of marker genotypes to numeric values

Genotype	Code
$\overline{G_1G_1}$	2
G_1G_2	1
G_2G_2	0

ightarrow Biological meaning of genotype code: count number of G_1 alleles

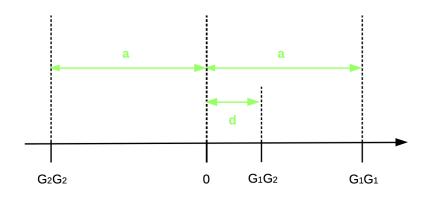

Genomic Regression

Model Fit

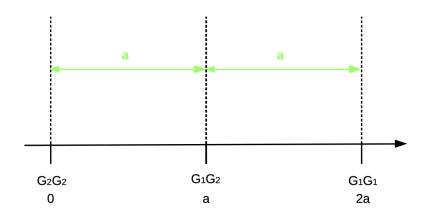

- \blacktriangleright Take only homozygous genotypes G_1G_1 and G_2G_2 from dataset
- ▶ Why only homozygotes? Look at extreme values for *d* with over- and under-dominance
- Fit regression line and compute marker effect a
- lacktriangle Shift x- axis, such that homozygotes have values -a and a
- lacktriangle Compute d as deviation of heterozygotes from 0

Single Locus Model

- Assuming $d=0 \to {\rm genotypic}$ value of G_1G_2 between homozygotes
- lacksquare Shifting origin to genotypic value of G_2G_2

Modified Single Locus Model

- Transformation of regression on genotypes to regression on number of "positive" alleles (G_1)
- Relationships imposed by regression are meaningful

Relationships

Expected value for observation for a given genotype

$$\begin{split} E(G_2G_2) &= b_0 + 0*a_G \\ E(G_1G_2) &= b_0 + 1*a_G \\ E(G_1G_1) &= b_0 + 2*a_G \end{split}$$

Differences

$$\begin{split} E(G_1G_2) - E(G_2G_2) &= E(G_1G_1) - E(G_1G_2) = a_G \\ E(G_1G_1) - E(G_2G_2) &= 2a_G \end{split}$$

Example Dataset

Exercise 5, Problem 1

Animal	SNP G	SNP H	Observation
1	G_1G_1	H_1H_2	510
2	G_1G_2	H_1H_1	528
3	G_1G_2	H_1H_1	505
4	G_1G_1	H_2H_2	539
5	G_1G_1	H_1H_1	530
6	G_1G_2	H_1H_2	489
7	G_1G_2	H_2H_2	486
8	G_2G_2	H_1H_1	485
9	G_1G_2	H_2H_2	478
10	G_2G_2	H_1H_2	479

Regression On Dummy Variables

- Cases that are not like genomic data
- Example with breeds
- Discrete independent variables are called **Factors** (e.g. Breed)
- Different values that a factor can take are called Levels
- Levels for our example factor Breed are: Angus, Limousin and Simmental

Levels To Independent Variables

Use "separate" x-variable for each level, hence each of the breeds

Breed	Independent Variable
Angus Limousin Simmental	$egin{array}{c} x_1 \\ x_2 \\ x_3 \end{array}$

Model

lackbox Observation y_{ij} stands for birth weight for animal j in breed i

$$\begin{split} y_{11} &= b_0 + b_1 * 1 + b_2 * 0 + b_3 * 0 + e_{11} \\ y_{12} &= b_0 + b_1 * 1 + b_2 * 0 + b_3 * 0 + e_{12} \\ \cdots &= \cdots \\ y_{33} &= b_0 + b_1 * 0 + b_2 * 0 + b_3 * 1 + e_{33} \end{split}$$

Sort animals according to breeds

Sorted Data

Animal	Body Weight	Breed
1	471	Angus
2	463	Angus
4	470	Angus
7	518	Limousin
8	511	Limousin
9	510	Limousin
10	541	Limousin
3	481	Simmental
5	496	Simmental
6	491	Simmental

Matrix - Vector Notation

$$y = Xb + e$$

with

- \blacktriangleright vectors y and e defined as in linear regression
- $lackbox{ vector }b$ contains intercept b_0 and separate effects for each breed

$$b = \left[\begin{array}{c} b_0 \\ b_{Angus} \\ b_{Limousin} \\ b_{Simmental} \end{array} \right]$$

Matrix X

 $lackbox{ Matrix } X$ is an incidence matrix linking factor levels to observations

$$X = \begin{bmatrix} 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 1 & 0 & 1 & 0 \\ 1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 \\ 1 & 0 & 0 & 1 \\ 1 & 0 & 0 & 1 \end{bmatrix}$$

Models Not Of Full Rank

Model

$$y = Xb + e$$

Least squares normal equations

$$\mathbf{X}^T\mathbf{X}\mathbf{b}^{(0)} = \mathbf{X}^T\mathbf{y}$$

Solutions

- matrix X not of full rank, use Matrix::rankMatrix() to check
- $\triangleright \mathbf{X}^T \mathbf{X}$ cannot be inverted
- solution

$$\mathbf{b}^{(0)} = (\mathbf{X}^T \mathbf{X})^{-} \mathbf{X}^T \mathbf{y}$$

where $(\mathbf{X}^T\mathbf{X})^-$ stands for a generalized inverse

Generalized Inverse

lacktriangle matrix ${f G}$ is a generalized inverse of matrix ${f A}$, if

$$AGA = A$$

$$(\mathbf{AGA})^T = \mathbf{A}^T$$

Use MASS::ginv() in R

Systems of Equations

For a consistent system of equations

$$Ax = y$$

Solution

$$x = Gy$$

if G is a generalized inverse of A.

$$x = Gy$$
$$Ax = AGy$$
$$Ax = AGAx$$

Non Uniqueness

ightharpoonup Solution x = Gy is not unique

$$\tilde{\mathbf{x}} = \mathbf{G}\mathbf{y} + (\mathbf{G}\mathbf{A} - \mathbf{I})\mathbf{z}$$

yields a different solution for an arbitrary vector ${\bf z}$

$$\mathbf{A}\tilde{\mathbf{x}} = \mathbf{A}\mathbf{G}\mathbf{y} + (\mathbf{A}\mathbf{G}\mathbf{A} - \mathbf{A})\mathbf{z}$$

Least Squares Normal Equations

lnstead of Ax = y, we have

$$\mathbf{X}^T\mathbf{X}\mathbf{b}^{(0)} = \mathbf{X}^T\mathbf{y}$$

lackbox With generalized inverse ${f G}$ of ${f X}^T{f X}$

$$\mathbf{b}^{(0)} = \mathbf{G}\mathbf{X}^T\mathbf{y}$$

is a solution to the least squares normal equations

Parameter Estimator

But $\mathbf{b}^{(0)}$ is not an estimator for the parameter \mathbf{b} , because

- it is not unique
- $\qquad \qquad \mathbf{E}(\mathbf{b}^{(0)}) = E(\mathbf{G}\mathbf{X}^T\mathbf{y}) = \mathbf{G}\mathbf{X}^T\mathbf{X}\mathbf{b} \neq \mathbf{b}$
